

I'm not robot!

5 months old baby feeding.

How can I securely safely install It will always be tricky. Please read the 5.5/5.6 compatibility page before doing anything. Mind 1 big difference between the 2: Beginning with MySQL 5.6.6, several MySQL Server parameters have defaults that differ from previous releases. The motivation for these changes is to provide better out-of-box performance and to reduce the need for the database administrator to change settings manually. These changes are subject to possible revision in future releases as we gain feedback. 1 of the big changes is that 5.5 uses 1 big file as a transactions log and 5.6 uses several. Therefore, if you are upgrading an existing MySQL installation, have not already changed the values of these parameters from their previous defaults, and backward compatibility is a concern, you may want to explicitly set these parameters to their previous defaults. For example, put these lines in the server option file: [mysqld] innodb.file_per_table=0 innodb.checksum_algorithm=INNODB binlog_checksum=NONE If you use replication pay attention to this part of the link: To upgrade servers used for replication, upgrade the slaves first, then the master. Replication between the master and its slaves should work provided that all use the same value of explicit defaults for timestamp: Bring down the slaves, upgrade them, configure them with the desired value of explicit defaults for timestamp, and bring them back up. The slaves will recognize from the format of the binary logs received from the master that the master is older (predates the introduction of explicit defaults for timestamp) and that operations on TIMESTAMP columns coming from the master use the old TIMESTAMP behavior. Bring down the master, upgrade it, and configure it with the same explicit defaults for timestamp value used on the slaves, and bring it back up. If this is a production server I would advice to first attempt this on a testing machine. We have had a rather difficult transition from 5.5 to 5.6 and opted to install another machine that was installed with 5.6 and use mysqldump to create backups and load them into our databases on that machine. Mind though that this will take a long time if you have a large database (due to the recreation of the innodb transactions files). A general method: use mysqldump to create backups of your database (users, table structure and table data) and of your config file (probably /etc/mysql/my.cnf) Remove 5.5. After removing 5.5 check that the innodb transactions files are gone (ibd*.i, ib_logfile0 and ib_logfile1). As 5.6 uses the better version of transactioning I assume you also would to use this... Install 5.6 Change the new config file and add in what you changed for 5.5 (mind though the link above and check if any of the changes have become invalid). Upload your backup into 5.6 (users first). Mind that this can take a bit of time since it will recreate new transaction files. In commands (after making the backup): sudo apt-get remove mysql-server sudo apt-get autoremove sudo apt-get install mysql-client-5.6 mysql-client-core-5.6 sudo apt-get install mysql-server-5.6 MySQL is an open-source database management system, commonly installed as part of the popular LAMP (Linux, Apache, MySQL, PHP/Python/Perl) stack. It uses a relational database and SQL (Structured Query Language) to manage its data. The short version of the installation is simple: update your package index, install the mysql-server package, and then run the included security and database initialization scripts. sudo apt-get update sudo apt-get install mysql-server sudo mysql secure installation sudo mysql install db This tutorial will explain how to install MySQL version 5.5, 5.6, or 5.7 on a Ubuntu 14.04 server. If you want more detail on these installation instructions, or if you want to install a specific version of MySQL, read on. However, if you're looking to update an existing MySQL installation to version 5.7, you can read this MySQL 5.7 update guide instead. Prerequisites To follow this tutorial, you will need: One Ubuntu 14.04 Droplet with a sudo non-root user. Step 1 — Installing MySQL There are two ways to install MySQL. You can either use one of the versions included in the APT package repository by default (which are 5.5 and 5.6), or you can install the latest version (currently 5.7) by manually adding MySQL's repository first. If you want to install a specific version of MySQL, follow the appropriate section below. To help you decide which version is best for you, you can read MySQL's introduction to MySQL 5.5, then what's new in MySQL 5.6 and what's new in MySQL 5.7. If you're not sure, you can just use the mysql-server APT package, which just installs the latest version for your Linux distribution. At the time of writing, that's 5.5, but you can always update to another version later. To install MySQL this way, update the package index on your server and install the package with apt-get. sudo apt-get update sudo apt-get install mysql-server You'll be prompted to create a root password during the installation. Choose a secure one and make sure you remember it, because you'll need it later. Move on to step two from here. Installing MySQL 5.5 or 5.6 If you want to install MySQL 5.5 or 5.6 specifically, the process is still very straightforward. First, update the package index on your server. Then, to install MySQL 5.5, install the mysql-server-5.5 package. sudo apt-get install mysql-server-5.5 To install MySQL 5.6, install the mysql-server-5.6 package instead. sudo apt-get install mysql-server-5.6 For both options, you'll be prompted to create a root password during the installation. Choose a secure one and make sure you remember it, because you'll need it later. Installing MySQL 5.7 If you want to install MySQL 5.7, you'll need to add the newer APT package repository from the MySQL APT repository page. Click Download on the bottom right, then copy the link on the next page from No thanks, just start my download. Download the .deb package to your server. wget Next, install it using dpkg. sudo dpkg -i mysql-apt-config 0.6.0-1_all.deb You'll see a prompt that asks you which MySQL product you want to configure. The MySQL Server option, which is highlighted, should say mysql-5.7. If it doesn't, press ENTER, then scroll down to mysql-5.7 using the arrow keys, and press ENTER again. Once the option says mysql-5.7, scroll down on the main menu to Apply and press ENTER again. Now, update your package index. Finally, install the mysql-server package, which now contains MySQL 5.7. sudo apt-get install mysql-server You'll be prompted to create a root password during the installation. Choose a secure one and make sure you remember it, because you'll need it later. Step 2 — Configuring MySQL First, you'll want to run the included security script. This changes some of the less secure default options for things like remote root logins and sample users. sudo mysql secure installation This will prompt you for the root password you created in step one. You can press ENTER to accept the defaults for all the subsequent questions, with the exception of the one that asks if you'd like to change the root password. You just set it in step one, so you don't have to change it now. Next, we'll initialize the MySQL data directory, which is where MySQL stores its data. How you do this depends on which version of MySQL you're running. You can check your version of MySQL with the following command. You'll see some output like this: Output mysql Ver 14.14 Distrib 5.7.11, for Linux (x86_64) using EditLine wrapper If you're using a version of MySQL earlier than 5.7.6, you should initialize the data directory by running mysql install db. Note: In MySQL 5.6, you might get an error that says FATAL ERROR: Could not find my-default.cnf. If you do, copy the /usr/share/my.cnf configuration file into the location that mysql install db expects, then rerun it. sudo cp /etc/mysql/my.cnf /usr/share/mysql/my-default.cnf sudo mysql install db This is due to some changes made in MySQL 5.6 and a minor error in the APT package. The mysql install db command is deprecated as of MySQL 5.7.6. If you're using version 5.7.6 or later, you should use mysqld --initialize instead. However, if you installed version 5.7 from the Debian distribution, like in step one, the data directory was initialized automatically, so you don't have to do anything. If you try running the command anyway, you'll see the following error: Output 2016-03-07T20:11:15.998193Z 0 [ERROR] --initialize specified but the data directory has files in it. Aborting. Regardless of how you installed it, MySQL should have started running automatically. To test this, check its status. You'll see the following output (with a different PID). Output mysql start/running, process 2689 If MySQL isn't running, you can start it with sudo service mysql start. For an additional check, you can try connecting to the database using the mysqladmin tool, which is a client that lets you run administrative commands. For example, this command says to connect to MySQL as root (-u root), prompt for a password (-p), and return the version. mysqladmin -p -u root version You should see output similar to this: Output mysqladmin Ver 8.4.2 Distrib 5.5.47, for debian-linux-gnu on x86_64 Copyright (c) 2000, 2015, Oracle and/or its affiliates. All rights reserved. Oracle is a registered trademark of Oracle Corporation and/or its affiliates. Other names may be trademarks of their respective owners. Server version 5.5.47-0ubuntu0.14.04.1 Protocol version 10 Connection Localhost via UNIX socket /var/run/mysqld/mysqld.sock Uptime: 4 min 15 sec Threads: 1 Questions: 602 Slow queries: 0 Opens: 189 Flush tables: 1 Open tables: 41 Queries per second avg: 2.360 This means MySQL is up and running. Conclusion You now have a basic MySQL setup installed on your server. Here are a few examples of next steps you can take:
